Liophant Simulation

DIME Genoa University

What are Validation and Verification?

- Validation is the process of determining whether the conceptual model is an accurate representation of the actual system being analyzed. Validation deals with building the right model.
- Verification is the process of determining whether a simulation computer program works as intended (i.e., debugging the computer program). Verification deals with building the model right.

The <u>Generic Methodology for Verification and Validation</u> (<u>GM-VV</u>) is devoted to:

- provide a generic framework to efficiently develop an argument
- provide a generic framework to justify why the product of M&S effort is acceptable for deployment in the target (intended) operational (use) context
- support stakeholders in their acceptance decision making process on the utilization of (M&S) products to satisfy their business goals
- provide support throughout the whole life-cycle of M&S product (development, employment and use/reuse)

GM-VV & M&S Community

- GM-VV has been designed to provide the M&S international community with a methodology for verification, validation and acceptance, which consistently embraces a wide variety of M&S technologies and application domains
- GM-VV support the community by a common language to better facilitate communication and co-operation between all participants in Verification, Validation and Acceptance endeavor

Unclassified, Unlimited Public Release

GM-VV Standard Base

- Many Standards for VV&A imply the use of a specific modeling and simulation (M&S) System Engineering paradigm, like for instance the (i.e. IEEE FEDEP)
- GM-VV is constructed over existing standards and common practices in System Engineering to facilitate the GM-VV application among M&S community

Simulation Development:

Simulation Development: VV&A.... and HBM

Simulation Development: VV&A... and HBM & Techniques

- The system of interest is organized into a hierarchical structure of sub-systems
- System components are defined to be the smallest parts of a system-of-interest the user wants to consider in the context of their own objectives
- A subsystem is considered to be a subset of components of a larger system

GM-VV Structure

The subsystem itself is a system which its own, on can subsequently be decomposed into subsystems as well

GM-VV Frame Structure

• A frame system is a formal specification of the operational use of a system-of-interest to meet its target objectives

A frame system, or experimental frame, is a dynamic system in itself and is therefore formalized also in Frame Input terms of a hierarchical decomposition of coupled and modular system components

GM-VV Measure of Merits

- The observed system output and the outcome measures could be utilized by the frame components for run-time assessment and feedback control of the system of interests
- Outcome measures could include Measures of Efficiency, Effectiveness, Performance or Merit (e.g. MOE, MOP,

MoM)

GM-VV System Evolution

The <u>System of Interest evolves</u> over time starting from defining the need for the system startup until its disposal. Such evolution consists of various phases in which the system maturity increases

GM-VV System Evolution Phases

- 1. Concept Phase results in an agreed specification of the system concept that has the prospect of meeting the system-of-interest intended use
- 2. Development Phase allows to transform the system concept into a system design
- **3. Production Phase** allows to produce the system in accordance the system design
- 4. **Operation Phase** include the deployment of the system and its put in operational service
- 5. Retirement Phase focuses on the timeframe when the system is taken out of service and any existing knowledge and experience gained with the system has to be consolidated in an archive

Simulator Development Needs

Just in Time on Simulator **Deliverables**

System Configuration Dynamics

DIME **Genoa University**

GM-VV Life Cycle

- A system progression through its life-cycle is obtained through coupled activities that may be invoked at any time of a system lifecycle by an organization
- Activities are not necessarily sequential, but are often performed parallel and in an iterative fashion
- The system engineering process can be system
 subdivided in four significant interrelated groups of processes

- E Evaluation Process Loop
- M Management Process Loop

Unclassified, Unlimited Public Release

GM-VV Organization Design

- The ORDIT (Organizational Requirements Definition Tool) in our case, for organizational requirements modeling technique, is a methodology for requirements and design specification of organizations
- Organizations are considered as an agent entity which is any size of group from an individual to a whole organization that takes part in a socio-technical system
- An agent can have a structural relationship with other agents in the socio-technical system, which implies a communication link to exchange information
- Structural relationships embody
 responsibility relationships between agents

ORDIT & Responsibilities

Responsibilities are specified in ORDIT In of: who terms is responsible to whom, state affairs for which of responsibility is held, list of obligations of responsibility holder and type or responsibility. In here obligations define in what the responsibility way holder is responsible, and what must be done to fulfill this responsibility

Responsibility Assignment Matrix

DIME

Genoa University

A=assist P=perform U=use R=responsible

RAM

The Responsibilities of the 4 actor types in context with the generation of the essential VV&A documents are shown in the table.

GM-VV Responsibility Management

 The ORDIT responsibility relationship provides the opportunity to delegate responsibilities by means of transferring obligations from one agent to another agent. When an agent transfers obligations to another agent he retains his initial responsibility for ensuing the state of affairs. This agent becomes a principle for this responsibility

GM-VV Agency

Agencies are specification of agents in terms of responsibilities and rights. Rights are the permissions or authorizations required to fulfill the agencies' responsibilities. Roles are specifications of agents in terms of obligations that they hold and capability tokens. Capability tokens specify the required access to resources in order to discharge the roles obligations. Resources specify the means for an agent needed to execute the activities. Rights capabilities tokens and resources thus specify organizational requirements to fulfill responsibilities

DIME Genoa University

GM-VV Configuration Management

VV&A of M&S is an iterative process within a M&S system lifecycle. In particular the reuse of M&S systems. Configuration Management of the VV&A products produced in this process is essential for a cost effective implementation of VV&A

Unclassified, Unlimited Public Release

GM-VV Three Pillars Paradigm

The *Three Pillars Paradigm* is the important and virtual concept of GM-VV. The three pillars paradigm address the theory and standards based on goal-driven project and quality management, organizations and processes

Organization

Liophant Simulation

GM-VV Pillars

- The paradigm addresses three different interrelated components, called pillars:
 - Product pillar contains one or more products that have to fulfill one or more goals in a target environment in which they will be employed. Products can have a life-cycle
 - Organizational pillar contains a social system of one or more agents (i.e. agencies and roles)
 - Process pillar contains one or more processes. A process is defined as a set of interrelated and interacting activities which transform inputs into outputs

Goal

Unclassified, Unlimited Public Release

Product

Process

GM-VV Frames

There are four world view inside GM-VV that represents the concept of **Problem Frame**. A problem frame is defined as a description of a recognizable class of problems which has a known solution. Problem frames provide a means to structure the world in which a problem is located and has to be solved

GM-VV SEM-SEF

DIME

Genoa University

Within GM-VV there are two distinct models: the *Simulation Executable Model* (*SEM*) and the *Simulation Experimental Frame* (*SEF*). These together are referred within GM-VV as the *M&S system*. This M&S system is considered in GM-VV to be a system that is the outcome of a system's life-cycle production phase. The SEM is the M&S development outcome that enables the actual replication of the *simuland* over time

GM-VV Simulation Executable Model

- The **SEM** is a complex dynamic system, which is composed of a set of coupled (sub) systems (federates, terrain model, weather model, visual system, motion system, etc.).
- A **SEM** is controlled and observed by ports (gray ovals). Through these ports simulation input and settings are entered, and simulation output leaving the **SEM** is observed
- The whole internal behavioral space of a **SEM** may not be controllable or observable or both. This poses certain limitations on VV&A endeavor

DIME

Genoa University

GM-VV Simulation Experimental Frame

- To be able to simulate the real-world properlies, the SEM is configured, controlled and stimulated by the simulation experimental frame (SEF) in terms of input trajectories, scenario's, parameters, experimental control settings, etc. As such the **SEF** is the operational implementation of the M&S intended use.
- In a **SEF** three possible interconnected components have been \bullet identified:
 - the observer
 - The analyzer
 - the generator

GM-VV Components

- The Observer watches, within the SEF, the SEM simulation output and preprocesses it before to send it to the Analyzer.
- This second object, the *Analyzer*, is the core of the SEF and is responsible for analyzing the preprocessed simulation output and transforming it into the required simulation results. Depending on the M&S intended use at hand, this transformation could be directly derived from a single simulation output trajectory or from multiple trajectories coming from different SEM runs. It is the analyzer object who decides on whether the user goals have been accomplished
- The *Generator* object stimulates the SEM with both simulation settings and input trajectories, based upon the output of the analyzer object

GM-VV VV&A World

- GM-VV considers VV&A of M&S as a separate problem frame or world with its own specific problems, issues and concerns though related with the M&S based problem solving approach,
- The objective of this VV&A world is the to provide the M&S system users and other stakeholders in the problem world a well-informed or wellargued acceptance recommendation to support their acceptance decision process needs regarding an M&S system in any phase of its life-cycle
- A VV&A stakeholder is an agent that will use the VV&A problem world outcome, being the acceptance recommendation, in the acceptance decision procedure to support decisions in the area of M&S system development, actual M&S employment and its results.

DIME

Genoa Universitv

Liophant Simulation

GM-VV VV&A Intended Use

- VV&A intended use, defines from the VV&A problem owner perspective, the usage of this acceptance recommendation and determines at which level the VV&A endeavor must be performed
- Depending on the VV&A intended use, the VV&A system of interest could be the simulation executable model, the simulation experimental frame, the M&S results, or any part(s) or combination(s)

GM-VV VV&A Frames

- The VV&A Frame Design and its Execution, by means of a well defined and controlled set of VV&A experiments, depend not only on the VV&A intended use, but on M&S intended use, use risk, cost, available human resources, M&S requirements and implementation constraints.
- The outputs of the frame are VV&A results that are used for building an appropriate acceptance recommendation

Unclassified, Unlimited Public Release

GM-VV Acceptability Criteria

- The Acceptability Criteria are defined upon the VV&A observables
- Four types of acceptability criteria are defined as properties in GM-VV:

Utility: Assesses the effectiveness and efficiency of the M&S system in solving the problem statement in the problem world. Evaluation metrics for utility comprise three areas: value or benefits (measures of effectiveness, measures of performance, etc.), costs (money, time, etc.) and use risks (impact, probability, etc.)

Validity: Assesses the level of agreement of the M&S system behavioral representation with that of the simuland. Validity metrics are also used to assess the consequences of any behavioral discrepancies on the utility of the M&S system

Correctness: Assesses whether the M&S system implementation conforms to the conceptual model, is free of error and of sufficient precision. Correctness metrics are also used to assess the consequences of implementation discrepancies on both the validity and utility of the M&S system

Meta-properties: Assesses the quality with which the utility, validity and correctness properties of a M&S system have been assessed. Among other meta-properties address aspects like balance, uncertainty, completeness, consistency, relevance, independency, reliability, and assumptions.

Liophant Simulation

Criteria & Features

Feature/Objective		Present	Example and Note			
1. User-Defined Initializing Para	ameters	YES	The user defined the profile of the Gang as well as the ROE to be used by Blue Units			
 Analyze Surrounding Envinto Capability 	oment and React Respectively	YES	The Blue Units encountering the Riot and the Gang takes actions to stop the looting			
3. Cooperation Capacity		YES	Some Blue unit are providing support on others reaching the demonstration/riot			
 Force Aggregating/Disaggre military hierarchy 	gating Capability and relevant	YES	Disaggregation of Blue unit in two Squads after dissolution of the Riot			
 Resultant Aggregation Level aggregating/disaggregating ele 	s different from ments sum/subtraction	YES	The combination of Demonstration and Gang looting create impact on the area different from the sum of the single entities and introduces the generation of a riot			
6. Limit Proper Autonomy to Ac Capability	hieve Common Objective	YES	It is possible to enable/disable the possibility for the Blue Unit to request direct support to the other ones and to let the scenario evolve with this other condition			
 Stress Level Indicator applic definition 	able for the entities behavior	YES	These aspects affect both Population and Military Units all along t simulation			
 Implementation of Typical He and moral/ethical motivations) 	uman Behavior (survival instinct	YES	It is possible to enable/disable the feature and check, versus critical riots, the different respect of ROE by Military Units			
Q Distinct Friend Foe and Neu	tral Units	YES	Distinction betweeen Gang and Militia			
ation Affected	Behavior	YES	Each entity provides a Log including the conditions under what each different ROE applied			
 Explosite 1 Explosite 2 	hmanders Capability	YES	Reporting that includes encounters with other units, Riots and situation evolution			
Las Facines 2		YES	Each entity provides a Log related to the factors affecting their actions			
		YES	Blue Unit moving among cells of an ethnic group affects the population evolution and the eventual creation of a Riot			
		YES	A single entity is representing the agitators that change the attitude of the demontration/riot			
		YES	The militia unit is corresponding to a team			
		YES	The Blue Unit in patrol corresponds to a Squad			
		YES	The Blue Unit providing support corresponds to a Platoon			
		YES	Reports about actions and events are distributed as interaction in the HLA Federation during Simulation Runs			

It is critical to guarantee proper VV for models especially with presence of HBM and Interoperability Issues

GM-VV Evidence Generation Process: Collecting Evidences

- For a proper demonstration of acceptability criteria, GM-VV should adopts an Evidence based Approach. This approach consists of two steps.
- The *first step is collecting relevant evidence* for the VV&A system of interest observables • related to the utility, validity, correctness and meta-properties by execution of VV&A experiments. Such a VV&A frame is union sub-frames, which are called evidence solutions at the most atomic subsystem level.
- An Oracle is the mechanism to generate the expected VV&A results from a local referent ٠ system or source. This type of VV&A results provides a set of reference data for the M&S system, to evaluate each property. Such data set is also commonly known as the VV&A referent. This results evaluation comprises a comparative analysis of the actual results with the expected results, which gives a qualification or quantification how well both match

DIME

GM-VV Evidence Generation Process: Using Evidences

- The Usage of the Evidence in a semi-formal reasoning to develop an *argument*(s) to justify the proposition or claim that a M&S system is acceptable or not is the second step. The resulting claim based argumentation network is known in GM-VV as the VV&A claim network. In this kind of reasoning also the quality of and the support by the collected data for utility, validity and correctness properties must be taken into account by assessment of their associated meta-property criteria
- Together with the VV&A intended use and VV&A goal network, this VV&A claim ٠ network provides the basis within GM-VV from which a well-informed and justified acceptance recommendation for the M&S system is developed. This acceptance recommendation is a VV&A problem owner oriented presentation of the VV&A claim network and all other relevant VV&A project information, which together comprise all needed information for adequate acceptance decision making on the M&S system and its deployment. GM-VV Matrix Processes

The GM-VV life-cycle processes consist are structured as following:

- Agreement Processes: comprises of two processes needed to establish a (sub)contractual agreement between a VV&A acquirer and supplier agency:
 - Acquisition Process

- Supply Process
- Enterprise Processes: comprises of five process needed to establish and maintain an enterprise or service-oriented environment within any VV&A agency:
 - Life Cycle Mngt. Process

- Infrastructure Mngt. Process
- Project Portfolio Mngt. Process
- Quality Management Process
- Human Resource Mngt. Process
- Project Processes: comprises of seven processes needed to establish and maintain
 - a VV&A project environment in which the technical processes are conducted
 - Project planning process
 - Decision management process
 - Configuration management process
 - Measurement process
- Technical Processes: comprises seven processes needed to do the actual technical work in order to produce or employ the required VV&A deliverables
 - VV&A requirements definition process VV&A requirements analysis process
 - VV design process

DIME

Genoa University

- VV integration process
- VV&A transition process

- VV implementation process

- Acceptance assessment process

- Project assessment and control process
- Risk management process
- Information management process

GM-VV Memory View

Liophant Simulation

- During VV&A projects a large amount of data and information needs to be processed and managed. This management and processing is a complex and time consuming task that is hard to be done by hand. Therefore, practical and cost-effective implementations of a rigorous and systematic VV&A methodology requires the availability of automated tools for information, knowledge, and configuration management.
- GM-VV specifies as an ٠ integral part of its methodology VV&A enabling two components; the VV&A corporate and project memory enabling components embody the pragmatic implementation of the VV&A information and knowledge management, and VV&A product configuration management in both project and enterprise environment

modes.

GM-VV Enterprise & Project Information Models

- The VV&A information models must facilitate both projects and enterprise environments, therefore two sets of interconnected information sub models are required:
 - VV&A Enterprise Information Model: shall specify and consolidate all enterprise management related information that is used to facilitate the execution of VV&A projects by a VV&A supplier agency. Among other things the core and VV&A specific subsystems of this information model are a VV&A cost model and a VV&A maturity model.

VV&A Project Information Model: shall specify and consolidate all project management related information that has to be produced and managed during the execution of a VV&A project. Among other things the core and VV&A specific subsystems of this information model are a VV&A project plan and project report. Furthermore, the VV&A project information model aggregates two other important sub-models: the VV&A agreement information model and VV&A technical information model. The VV&A agreement information model contains the VV&A contract and other contractual agreement information for the VV&A project. The VV&A technical information model specifies all technical information that will be developed during the execution of a VV&A project.

- GM-VV represents a methodology proposing process, guidelines, criteria and a common vocabulary for supporting acceptability of models, simulations
- GM-VV refers to System Engineering Standards to guarantee the widest generic approach to be applied to M&S Products
- GM-VV embraces among the others the VV&A processes
